Image Multi-Thresholding By Combining The Lattice Boltzmann Method and Level Set Method Of Active Contour for Image Segmentation Using Fuzzy Clustering

Narahari Anudeep Reddy¹, Polala Narsimulu², M.Raju³

Abstract— During the last decades, the development of high dimensional large-scale imaging devices increases the need of fast, accurate and parallelizable segmentation methods. Due to its intrinsic advantages such as its ability to handle complex shapes, the level set method (LSM) has been widely used. In this paper, Lattice Boltzmann Method (LBM) has been proposed to simulate the well known active contour model (the CV model) for image segmentation. The proposed method provides a new numerical solution for solving the level set equation of the active contour model. As a local and explicit scheme, the algorithm based on LBM is not only stable with large steps, but also overcomes the difficulty in parallel computing of most implicit difference approaches. Experimental results demonstrate that LBM is computationally more efficient than the semi-implicit discrete method of CV model.

Index Terms— Fuzzy c-means (FCM), image segmentation, intensity inhomogeneity, lattice Boltzmann method (LBM), level set equation (LSE), partial differential equation (PDE).

I. INTRODUCTION

Image segmentation is an important processing step in many image, video and computer vision applications. Extensive research has been done in creating many different approaches and algorithms for image segmentation, but it is still difficult to assess whether one algorithm produces more accurate segmentations than another, whether it be for a particular image or set of images, or more generally, for a whole class of images. It is often used to partition an image into separate regions, which ideally correspond to different real-world objects. Many segmentation methods have been developed, but there is still no satisfactory performance measure, which makes it hard to compare different segmentation methods, or even different parameterizations of a single method. The level set method (LSM) is a part of the whole family of active contour methods (ACMs). The key idea that started the level set fanfare was the Hamilton–Jacobi approach, i.e., a time-dependent equation for a moving surface. This was first done in the seminal work of Osher and in 2-D space, the LSM represents a closed curve in the plane as the zero level set of a 3-D function $\varnothing$. For instance, starting with a curve around the object to be detected, the curve moves toward its inner normal and has to terminate on the boundary of the image. Two approaches are usually used to stop the evolving curve on the boundary of the desired object; the first one uses an edge indicator depending on the gradient of the image like in classical snakes and ACMs [2]–[5], [21], [31], and the second one uses some regional attributes to stop the evolving curve on the actual boundary [22], [23], [32] where the authors extend the representative region-based level set from scalar to tensors by simultaneously taking into account the pixel’s gray level and some local statistics such as gradient and orientation. The latter is more robust against noise and can detect objects without edges.

In addition, the Chan Vese (CV) method is not suitable for parallel programming because, at each iteration, the average intensities inside and outside the contour should be computed, which increases drastically the CPU time by increasing communications between processors. For this purpose, we propose a new method which tries to overcome the aforementioned drawbacks. Our method is based on a new idea which aims to stop the evolving curve according to the membership degree of the current pixel to be inside or outside of the active contour. This is done with the help of the modified fuzzy C-means (FCM) objective function obtained in [19] which also takes into consideration the shading image due to the intensity inhomogeneity.

The proposed method is based on the approach of the LBM PDE solver defined in [14]. In our proposed method, using a modified FCM objective function, we design a new fuzzy external force (FEF). The method is fast, robust against noise, and efficient whatever the position or the shape of the initial contour and can detect efficiently objects with or without edges. It has, first, the advantage of the FCM which gives it the latitude to stop the evolving curve according to the membership degree of the current pixel, second, the advantages of the LSM which allow it to handle complex shapes, topological changes, and different constraints on the contour smoothness, speed, size, and shape which are easily specified, and, third, the advantages of the LBM which make it very suitable for parallel programming due to its local and explicit nature.
II BACKGROUND

The proposed method uses mainly two techniques belonging to different frameworks: the LSM and the LBM.

A. LSM

The LSM is a numerical technique for tracking interfaces and shapes. Using an implicit representation of active contours, it has the advantage of handling automatically topological changes of the tracked shape. The evolution of the curve starts from an arbitrary starting contour and evolves itself driven by the LSE which can be seen as a convection–diffusion equation typically develops irregularities during its evolution, which may cause numerical errors and eventually destroy the stability of the evolution. Therefore, a numerical remedy, called reinitialization, is typically applied to periodically replace the degraded level set function with a signed distance function. The level set function.

\[
\frac{\partial \phi}{\partial t} + \nabla \cdot (\phi \mathbf{v}) = b \Delta \phi
\]  

(1)

The evolution of the curve starts from an arbitrary starting contour and evolves itself driven by the LSE level set methods have been used to solve a wide range of scientific and engineering problems, their applications have been plagued with the irregularities of the LSF that are developed during the level set evolution. In conventional level set methods,

\[
\frac{\partial \phi}{\partial t} + \nabla \cdot (\phi \mathbf{v}) = b k |\Delta \phi|
\]  

(2)

Being an alternative method for solving PDE, the LBM has several advantages, such as parallelizability and simplicity.

B. LBM

The LBM is a numerical framework for modeling Boltzmann particle dynamics on a 2D or 3D lattice [13]. It was first designed to solve macroscopic fluid dynamics problems [14]. The method is second order accurate both in time and in space, and in the limit of zero time step and lattice spacing, it yields the Navier Stokes equations for an incompressible fluid [15].

Fig. 1: Spatial structure of the D2Q9 LBM lattice.

The proposed method uses the D2Q9 (2-D with eight links with its neighbors and one link for the cell itself) LBM lattice structure. Fig. 1 shows a typical D2Q9 model. Each link has its velocity vector \( \mathbf{e}_i \) \((\vec{r}, \vec{r} + \vec{e}_i, t + 1) \) and the particle distribution \( f_i(\vec{r}, t) \) that moves along this link, where \( \vec{r} \) is the position of the cell, and \( t \) is the time. The LBM evolution equation can be written as follows using the Bhatnagar, Gross, and Krook collision model [7].

\[
f_i(\vec{r} + \vec{e}_i, t + 1) = f_i(\vec{r}, t) + \frac{1}{\tau} \left[ f^{eq}_i(\vec{r}, t) - f_i(\vec{r}, t) \right]
\]  

(3)

where \( \tau \) represents the relaxation time determining the kinematic viscosity \( \nu \) of the fluid by

\[
\nu = \frac{1}{3} \left( \frac{1}{2} \right)
\]  

(4)

and \( f^{eq}_i \) is the equilibrium particle distribution defined as \( f^{eq}_i(\rho, \mathbf{u}) = \rho (A_i + B_i (\mathbf{e}_i \cdot \mathbf{u}) + C_i (\mathbf{e}_i \cdot \mathbf{u})^2 + D_i (\mathbf{u})^2) \)

(5)

Where \( A_i \) to \( D_i \) are constant coefficients depending on the geometry of the lattice links and \( \rho \) and \( \mathbf{u} \) are the macroscopic fluid density and velocity, respectively, computed from the particle distributions as

\[
\rho = \sum_i f_i \quad \mathbf{u} = \frac{1}{\rho} \sum_i f_i \mathbf{e}_i.
\]  

(6)

For modeling typical diffusion computations, the equilibrium function can be simplified as follows [14]:

\[
f^{eq}_i(\rho, \mathbf{u}) = \rho A_i.
\]  

(7)

In the case of D2Q9 model, \( A_i = 4/9 \) for the zero link, \( A_i = 1/9 \) for the axial links, and \( A_i = 1/36 \) for the diagonal links. Now, the relaxation time \( \tau \) is determined by the diffusion coefficient \( \gamma \) defined as

\[
\gamma = \frac{2}{9} (2\rho - 1)
\]  

(8)

As shown in [14], LBM can be used to solve the parabolic diffusion equation which can be recovered by the Chapman–Enskog expansion

\[
\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v}) = \gamma \nabla \cdot \mathbf{v}
\]  

(9)

In this case, the external force can be included as follows:

\[
f_i = f_i + \frac{2\tau}{\gamma} B_i (\mathbf{v} \cdot \mathbf{e}_i)
\]  

(10)

Moreover, thus, (9) becomes

\[
\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v}) + \mathbf{F}.
\]  

(11)

Replacing \( \mathbf{v} \) by the signed distance function, the LSE can be formed

III. PROPOSED METHODOLOGY

This section details first the conception of the FCM-based energy function from which we deduce the corresponding LSE. We then set the FEF. Moreover, finally, we implement the proposed

A. Energy Function Design

In the image segmentation context, the standard FCM algorithm is an optimization problem for partitioning an image of \( N \) pixels, \( X = \{x_i\}_{i=1}^{N} \), into \( c \) classes. It aims to minimize a clustering criterion as [7]

\[
J(U, V, X) = \sum_{k=1}^{c} \sum_{i=1}^{N} u_{ik}^p \|x_i - v_k\|^2
\]  

(1)
Where $U$ is the partition matrix whose element $u_{ki}$ is the membership of the $i$th voxel for $k$th class. $V$ is the centroid vector whose element $v_k$ is the centroid (or prototype) of $k$th class. The parameter $p$, is the index for fuzzy, is an exponent for weighting on membership in each fuzzy set and determines the amount of “fuzziness” of the resulting segmentation. The norm operator represents the standardized Euclidean distance. The objective function $J$ is decreased when high membership values are assigned to the pixels whose intensities are close to the centroid of its particular class and low membership values are assigned to the pixels whose intensities are far from the centroid. As done in [7], the bias field is incorporated into the FCM framework by modeling the observed image as follows:

$$Y_i = X_i G_i, \forall i \in \{1, 2, \ldots, N\}$$

Where $Y_i$, $X_i$, and $G_i$ are the observed intensity, true intensity, and gain field at the $i$th pixel, respectively. $N$ is the total number of pixels in the magnetic resonance image. The artifact can be modeled as an additive bias field by applying a logarithmic transformation to both sides of (13) [7], [8]

$$y_i = x_i + \beta_i, \forall i \in \{1, 2, \ldots, N\}$$

Where $y_i$ and $x_i$ are the observed and true log-transformed intensities at the $i$th voxel, respectively, and $\beta$ is the bias field at the $i$th voxel. By incorporating the bias field model into an FCM framework, we will be able to iteratively estimate both the true intensity and the bias field from the observed intensity. By substituting (14) into (12), the clustering criterion to minimize in the presence of bias field becomes a constrained optimization problem.

$$J(U, V, B, Y, \phi) = \sum_{k=1}^{N} u_{ki}^p \| y_i - \beta_i - v_k \|^2$$

s.t. $\sum_{k=1}^{K} u_{ki} = 1, \forall i, 0 \leq u_{ki} \leq 1, \forall k, i$

Where $Y = \{Y_i\}_{i=1}^{N}$ is the observed image and $B = \{B_i\}_{i=1}^{N}$ is the bias field image. In a continuous form, the aforementioned criterion can be written as

$$J(U, V, Y, \phi) = \sum_{k=1}^{K} \int_{\Omega_k} U_k(x,y) \| Y(x,y) - B(x,y) - v_k \|^2 dx$$

s.t. $\sum_{k=1}^{K} U_k(x,y) = 1, \forall \Omega_k, 0 \leq U_k(x,y) \leq 1, \forall \Omega, x, y$. 

Consider the two-phase level set although the method can be easily extended to more than two phases. The image domain $\Omega$ is segmented into two disjoint regions $\Omega \Omega_1$ and $\Omega_2$, i.e., $c = 2$. In this case, we can introduce a level set function as follows:

$$J(U, V, B, Y, \phi) = \sum_{k=1}^{K} \int_{\Omega_k} U_k(x,y) \| Y(x,y) - B(x,y) - v_k \|^2 dx$$

s.t. $U_1(x,y) + U_2(x,y) = 1, \forall \Omega, 0 \leq U_k(x,y) \leq 1, \forall \Omega, x, y$. 

Where $\phi$ is a signed distant function. The aforementioned term $J(U, V, B, Y, \phi)$ is used as the data link in our energy functional which is defined as follows:

$$E(U, V, B, Y, \phi) = J(U, V, B, Y, \phi) + \nu |C|$$

where $\nu |C|$ is a regularization term with $\nu \neq 0$ being a fixed parameter and $C$ being a given curve which is represented implicitly as the zero level of $\phi$ and $|C|$ is the length of $C$ and can be expressed by the following equation [9]

$$|C| = \int \| \nabla \phi \| dxdy.$$ 

B. LSE

As done in [10], to obtain the LSE, we minimize $E(U, V, B, Y, \phi)$ with respect to $f$. For fixed $U$, $V$, and $B$, we use the gradient descent method

$$\frac{\partial E}{\partial f} = \frac{\partial (\phi)}{\partial f} \left( U(x,y) |Y(x,y) - B(x,y)|^2 - U_k(x,y) |Y(x,y) - B(x,y) - v_k|^2 \right) + \nu \delta(\phi) \text{div} \left( \frac{\nabla \phi}{|\nabla \phi|} \right)$$

$$s.t. U_1(x,y) + U_2(x,y) = 1, \forall \Omega, x, y.$$ 

However, for solving the minimization problem of $E(U, V, B, Y, \phi)$, we should also compute the first derivatives of $E(U, V, B, Y, \phi)$ with respect to $u_{ki}$, $v_k$, and $\beta$ and set them equal to zero. We thus obtain three necessary conditions

$$0 = \frac{\partial E}{\partial u_{ki}} = u_{ki} \left( \int \frac{U_k(x,y) |Y(x,y) - B(x,y)|^2}{\sum_{k=1}^{K} U_k(x,y)} dxdy - \sum_{k=1}^{K} U_k(x,y) v_k \right)$$

$$0 = \frac{\partial E}{\partial v_k} = v_k \left( \int \frac{U_k(x,y) |Y(x,y) - B(x,y) - v_k|^2}{\sum_{k=1}^{K} U_k(x,y)} dxdy - \sum_{k=1}^{K} U_k(x,y) \beta_k \right)$$

$$0 = \frac{\partial E}{\partial \beta_k} = \beta_k \left( \int \frac{U_k(x,y) |Y(x,y) - B(x,y)|}{\sum_{k=1}^{K} U_k(x,y)} dxdy - \sum_{k=1}^{K} U_k(x,y) \beta_k \right)$$

C. LATTICE BOLTZMANN SOLVER FOR LSE

By using the gradient projection method of Rosen [17], we can replace $d(\Omega)$ by $|\Omega|$ in the proposed LSE, and as $\Omega$ is a distance function, we have $|\Omega| = 1|\Omega|$, [16], [20] and will stay at each step since an adaptive approach is not used and the distant field is valid in the whole do main [25]. Thus, the proposed LSE becomes

$$\frac{\partial \phi}{\partial t} = \int \left( \frac{U_k(x,y) |Y(x,y) - B(x,y)|^2}{\sum_{k=1}^{K} U_k(x,y)} \right) dxdy - \int \left( \frac{U_k(x,y) |Y(x,y) - B(x,y) - v_k|^2}{\sum_{k=1}^{K} U_k(x,y)} \right) dxdy + \nu \text{div} \left( \frac{\nabla \phi}{|\nabla \phi|} \right)$$
\[ s.t. \ U_1(x, y) + U_2(x, y) = 1 \ \forall x, y \]

\[ \text{Replace } \rho \text{ by the signed distance function } \phi, (11) \text{ becomes } \]

\[ \frac{\partial \phi}{\partial t} = \gamma \text{div}(\nabla \phi) + F. \]

By setting the external force

\[ F = \lambda \left( U_1^2(x, y) |Y(x, y) - B(x, y) - v_1|^2 - U_2^2(x, y) |Y(x, y) - B(x, y) - v_2|^2 \right) \]

Where \( \lambda \) is a positive parameter; we can see that (25) is only a variational formula of (26) and, thus, can be solved by the LBM with the above-defined FEF. The choice of parameter \( p \) is at great importance for the segmentation result. Distinct values for \( p \) will result in the divergent results, as following:

i If \( p > 2 \), then the exponent \( 2/(p - 1) \) in (22) decreases the membership value of the pixels that are close to the centroid. The segmentation result will therefore be wrong since it is intuitively better that the membership value be high for those pixels who are close to the centroid.

ii If \( p \to 2 \), a II the membership values tend to 1/c. This implies that the FEF becomes

\[ \text{EFF} \to \lambda \left( \frac{1}{c^p} |Y(x, y) - B(x, y) - v_1|^2 - \frac{1}{c^p} |Y(x, y) - B(x, y) - v_2|^2 \right) \to 0. \]

There is, therefore, no link with the image data in the LSM process. Therefore, segmentation is impossible

iii If \( p \to 1 \), the exponent \( 2/(p - 1) \) increases the membership values of the pixels who are closed to the centroid. As \( p \to 1 \), the membership tends to one for the closest pixels and tends to zero for all the other pixels. This case is equivalent to the use of the k-means objective function instead of the FCM one. The segmentation is therefore rigid, and we lose the advantage of FCM over k-means. For all these reasons, a suitable choice of the parameter \( p \) can be the value of two, which is therefore used in all our experiments.

IV. IMPLEMENTATION

When using LBM to resolve the convection–diffusion equation, the particle density is set as \( \phi \) which is a signed distance function. Since the particle density of the cell cannot be negative, we modify the distance function as:

\[ \phi' = \phi - \min(\phi). \]

The contour is those pixels satisfying \( \phi' = -\min(\phi) \), which satisfy. The steps for the computation are outlined as follows:

i Initialize the distance function \( \phi \) and class centroid values \( v_1 \) and \( v_2 \). Initialize B with zeros.

ii Compute \( U_1^F(\vec{x}, \vec{y}) \) and \( U_2^F(\vec{x}, \vec{y}) \) with (22).

iii Compute \( v_1 \) and \( v_2 \) with (23).

iv Compute B with (24).

v Compute the external force with (27).

vi Include the external force based on (10).

vii Resolve the convection diffusion equation with LBM with (3).

viii Accumulate the \( f_i(G^2, \epsilon) \) values at each grid point by (6), which generates an updated distance value at each point.

ix Find the contour.

X If the segmentation is not done, increase the value of \( \lambda \) and go back to step 5.

We should notice that the \( B \) obtained from (24) is a “residual” image but not necessarily the bias field.

V. EVALUATION OF THE PROPOSED METHOD

In order to objectively measure the quality of the segmentations produced, three evaluation measures are considered in this paper. The first one is the Probabilistic Rand Index (PRI, [21]). This index compares results obtained from the tested algorithm to a set of manually segmented images. Since there is not a single correct output, considering multiple results allows to enhance the comparison and to take into account the variability of human perception.

The PRI is based on a soft non uniform weighting of pixel pairs as a function of the variability in the ground-truth. The ground-truth set is defined as \( \{G_1, G_2, \ldots, G_l\} \) where \( L \) is the number of manually segmented images. Let \( S \) be the segmentation provided by the tested algorithm, the label of pixel \( x_i \) in the \( k \)-th manually segmented image and the label of pixel \( x_i \) in the tested segmentation. Then, PRI is defined by

\[ \text{PRI}(S, G_k) = \frac{2}{N(N - 1)} \sum_{i,j=1}^{L} (p_{ij}^c - p_{ij}) p_{ij}^{c} \]

Where \( N \) is the number of pixels, \( c \) is a Boolean function denoting if \( \text{IF}_{i} \) is equal to \( \text{IF}_{ij}^c \) and \( p_{ij} \) is the expected value of a Bernoulli distribution for the pixel pair. The PRI metric is in the range \([0, 1]\), where high values indicate a large similarity between the segmented images and the ground-truth. The second one is the Variation of Information (VOI, [15]). The VOI metric measures the sum of information loss and gain between two clustering belonging to the lattice of possible partitions. It is defined by

\[ \text{VOI}(S, G_k) = H(S) + H(G_k) - 2 I(S, G_k). \]

Where \( H \) is the entropy \( -\sum_{j} n_{ij} \log n_{ij} \), \( n_{ij} \) being the number of points belonging to the \( i \)-th cluster. The term \( I \) is the mutual information between two clustering, and it is defined by

\[ I(S, G_k) = \sum_{i=1}^{L} \sum_{j=1}^{L} n_{ij} \log \frac{n_{ij} n_{ij}}{n_i n_j} \]

Where \( n_{ij} \) is the number of points in the intersection of cluster \( i \) of \( S \) and \( j \) of \( G_k \). The VOI measure is a distance, therefore the smaller it is, the closer the segmentation obtained and the ground-truth are.

The Global Consistency Error (GCE [14]) evaluates to what extent a segmentation can be viewed as the refinement of the other. A measure of error at each pixel \( x_i \) is defined by

\[ E(S, G_k, x_i) = \left| \frac{R(S, x_i) \setminus R(G_k, x_i)}{|R(S, x_i)|} \right| \]

Where \(| \) is the cardinality, \( \setminus \) is the set difference, and \( R(S, x_i) \) is the set of pixels corresponding to the region in segmentation \( S \) that contains the pixel \( x_i \). The GCE measure, which forces all local refinements to be in the same direction, is then defined by
The closer $GCE$ is to zero, the better the segmentation $S$ with respect to the ground-truth $G_k$.

Now in the remaining part of this section we will present the results obtained from the developed work. For the proper evaluation of the developed method three images have been used for example figure (5.1) and figure (5.2) shows the first input image and its segmentation using proposed work. Table 1 contains the three parameter values obtained after segmentation using proposed method.

VI. EXPECTED OUTCOME

This project work will brought forward a new Lattice Boltzmann Method (LBM) has been proposed to simulate the well known active contour model (the CV model) for image segmentation. On the basis of nature of segmentation...
parameters we expects this proposed frame work will leads to an efficient solution for object segmentation for color images.

VII. CONCLUSION AND FUTURE WORK

This paper presents a level set image segmentation method based on the idea of stopping the evolving contour according to the degree of membership of the active pixel to be inside or outside of this evolving contour. It is done with the help of the FCM partition matrix. The LSE is solved by using the powerful, simple, and highly parallelizable LBM which allows the method to be a good candidate for GPU implementation. The method gives promising results. Experimental results on medical and real-world images have demonstrated the good performance of the proposed method in terms of PRI, VOI and GCE. It presents a fast and efficient comprehensive implementation for gray image segmentation. It aims to aims maximize PRI value where as to minimize VOI and GCE value. According to an extensive comparison with state of the art segmentation methods, this approach gives satisfactory results. The PRI, VOI, GCE value calculated for different images is found to be in a specific desired range which shows the successful implementation of the method. Future works can be an implementation of the proposed method for color images in order to fully take advantage of the LBM. GCE and VOI can be reduced more to segment the image more accurately.
